

Interferometric Imaging and Stellar Interferometry at JPL

Peter R. Lawson

California Institute of Technology
Jet Propulsion Laboratory

January 26, 2001

Why Interferometry?

1: Imaging resolution

- λ/B for an interferometer vs. λ/D for a telescope
- **B**, separation of apertures, can cost-effectively be made very large

2: Astrometric accuracy

- Interferometers have a simple geometry which can be accurately monitored to minimize systematic errors
- Interferometers use starlight efficiently

3: High dynamic range capability

- Interferometers have the ability to “null starlight” with extreme precision
- Allows detection of planets or other dim objects orbiting a star

Figure 13.5 The 100 inch (2.5 m) Hooker reflector on Mount Wilson, completed in 1917. (Courtesy The Observatories of the Carnegie Institution of Washington.)

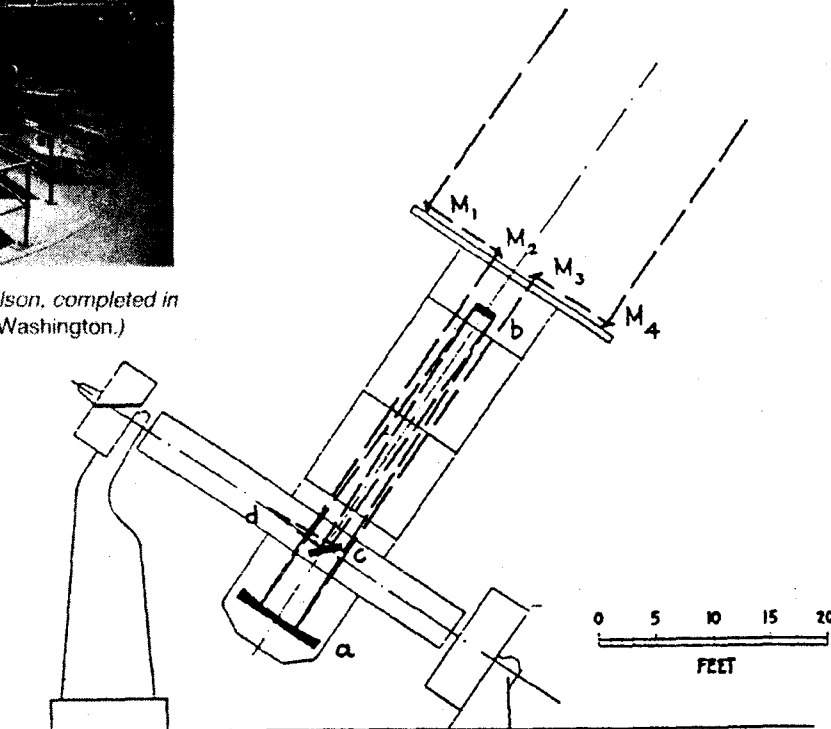

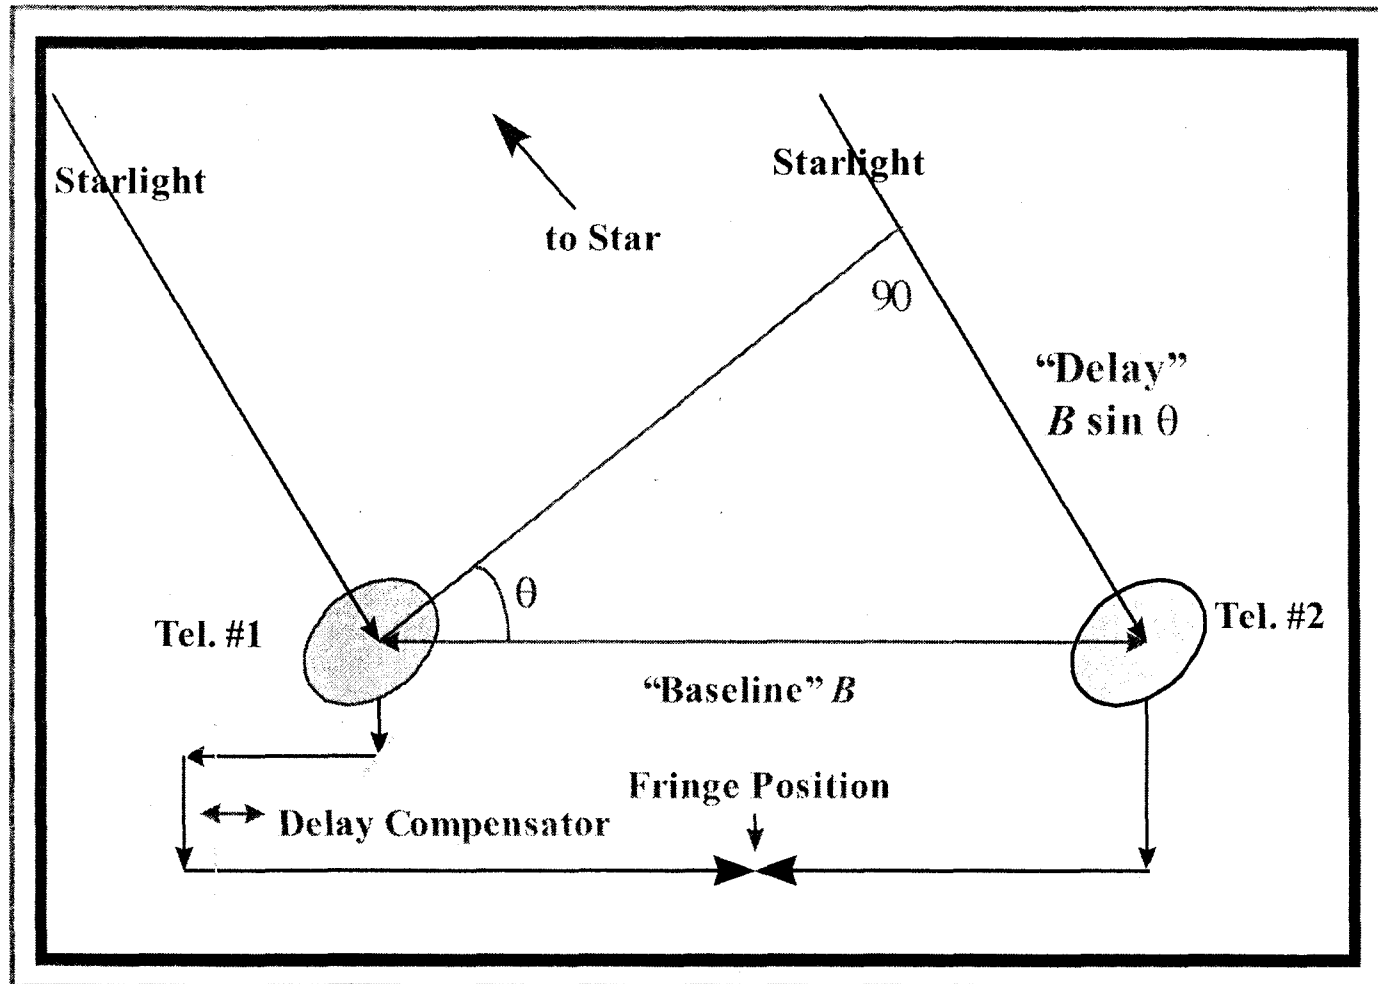

FIG. 1.—Diagram of optical path of interferometer pencils. M_1 , M_2 , M_3 , M_4 , mirrors; a , 100-inch paraboloid; b , convex mirror; c , coudé flat; d , focus.

NASA's Astronomical Search for Origins

To understand how galaxies formed in the early universe and to determine the role of galaxies in the appearance of stars, planetary systems and life.

To understand how stars and planetary systems form and to determine whether life-sustaining planets exist around other stars.

To understand how life originated on Earth and to determine if it began and may still exist elsewhere as well.

Astrometric Search for Planets

- Astrometry measures positional wobble due to planets
 - More sensitive than RV
 - no $\sin(i)$ ambiguity
- Interferometry will enable measurements at the micro-arcsecond level
 - Earth at 10 pc produces $0.3 \mu\text{as}$ amplitude
- Result of new observing systems will be a census of planets down to a few M_{earth} over the next 10-20 years

Narrow Angle Astrometry

- Planet detection: “Jupiter” at 10 pc produces a 1 mas peak-to-peak star wobble.
- $20 \mu\text{as}$ astrometry possible from the ground over narrow angles.

Keck Interferometer

JPL

- Interferometry with the two 10-m Keck telescopes and four 1.8-m outrigger telescopes
- Funding from NASA as part of the Origins Program
- Joint development between JPL and CARA
- Funding started in Oct 1997 (FY98); CDR: Aug '98

Astrometric Detection of Exoplanets

- Science objective
 - Survey 100's of nearby stars for planets to Uranus mass
 - Uses outrigger telescopes for long-term survey
- Approach
 - High-accuracy narrow-angle astrometry
- Configuration
 - 4 1.8-m outriggers
 - Orthogonal >100m baselines
 - Dual-star feeds
 - End-to-end laser metrology
 - 30 μ as per hour accuracy for differential astrometry
 - Uses K17 isoplanatic ref.

Imaging

- Imaging with 6-element array
- Good (u,v)-plane coverage
- 9 of 15 baselines include a 10-m telescope
 - Background-limited sensitivity equivalent to two 4.4-m's
 - Other imaging options using OTs with 1 or 0 Kecks
- Use cophasing to increase sensitivity
- Ultimate sensitivity
 - K-K fringe tracking: K14.1
 - OT-OT fringe tracking: K10.8
 - Cophased imaging
 - K19 for SNR >10 in 1000 s on a Keck-OT baseline
 - Requires K11.6 isoplanatic ref

u,v coverage with outriggers and Kecks
(width of line indicates baseline)

Science and cophasing baselines

— cophasing
--- science

Siderostats

JPL

- Siderostats installed & operational on summit
- Beam transport mirrors aligned & star acquired in basement

Basement Infrastructure Installation

JPL

Hardware

JPL

•Long delay lines

•Fringe tracker

•Fast delay lines

•Laser metrology

•Beam combiner

•Nuller

Space Interferometry Mission

Technology

Science *

technology maturation
over the next few years
to define the ultimate
achievable performance

Space Interferometry Mission (SIM)

JPL

Wide angle astrometric accuracy	4 μ as (5 yr)
Narrow angle astrometric accuracy	1 μ as (1 hr)
Instrument field of regard	15 degrees
Instrument throughput (V=16 star)	5.8 μ as (10 min)
Synthesis Imaging Resolution	10 mas
Nulling Depth	10 ⁻⁴

SIM Configuration

JPL

Nanometer Control Testbed

Flexible truss ~5 hz resonance
Simulated spacecraft disturbance (reaction wheels)
Active isolation of disturbance & active optical loop
(using laser interferometry as the sensor)

SIM System Testbed (STB-3)

JPL

Now: 3 baselines on optical table

- Three interferometers functioning on an optical table
- Completed detailed design of SIM-scale flexible structure to be built and installed by end-2000

Soon: 3 baselines on structure

- Begin nanometer active control experiments on flexible structure
- Three baselines, full scale

Picometer measurement technology

Component technologies

- *superprecise optical elements*
- *picometer laser gauges*
- *frequency stabilized lasers*

Microarcsec Metrology Testbed

- *fully functional interferometer tested in vacuum at picometer levels*
- *verify testing procedure for flight hardware*

Multiple Spacecraft Interferometry ST-3 Technology Mission

- The New Millennium Program ST-3 Mission will provide validation of key enabling technologies for TPF
 - Separated S/C interferometry
 - Precision formation flying
 - Real-time optical control of a separated S/C interferometer
 - Angular and linear metrology
 - Inertial referencing for phasing and guiding
 - Separated S/C interferometer I&T techniques

ST3 Launch Stack Configuration

JPL

Mission Timeline

Cluster checkout

S/C separate and perform
formation flying checkout &
experiments
Combiner mode interferometry
checkout, experiment & observations

Delta 2925 Launch - September 2005
Heliocentric Earth trailing orbit

Separated spacecraft
interferometry checkout
experiments & observations
Formation flying experiments

Flight System On-Orbit Configuration

Two Spacecraft Interferometer Concept

P. Gorman B/27/98

- S/C separation from 50 m to 1 km
 - Observation baselines of 40 to 200 m
 - 8th magnitude stellar targets
- Parabola is locus of constant delay
- Combiner contains 20 m fixed delay line
- Combiner can operate as a 1 m monolithic interferometer
 - No collector, bypass fixed delay

Context Diagram

Formation Interferometer Testbed

JPL

1999

Active Delay Line

Main combiner bench

- Facility complete: cleanliness tested to $< 10,000$
- Breadboard H/W integrated
- Software integration in progress

Terrestrial Planet Finder (TPF)

- Direct detection of Earth-like planets around nearby stars
- Approach
 - Interferometric starlight nulling by $\sim 10^6$ to detect 10 μm infrared light from the planet
 - ~ 10 hrs of observation to detect an Earth-like planet at 10 pc
 - 2-4 weeks to measure a low resolution spectra of the atmosphere, to identify H_2O , CO_2 , O_3
- Configuration
 - 4 large ($\sim 3\text{m}$) collecting apertures
 - Cryogenically-cooled optics
 - Formation flying to provide baselines of 50 - 500 m

Nulling Interferometry

LONG BASELINE STELLAR INTERFEROMETERS

Operational Ground-Based Interferometers

- CHARA Array - Center for High Angular Resolution Astronomy Array (Mt Wilson, California; GSU).
- COAST - Cambridge Optical Aperture Synthesis Telescope (MRAO, UK).
- FLUOR - Fiber Linked Unit for Optical Recombination (Obs. de Paris, France).
- GIZT/BEGAIN - Grand Interféromètre à 2 Télescopes (Obs. de Calern, France).
- IOTA - Infrared-Optical Telescope Array (Whipple Obs., Arizona). [Photo](#).
- ISI - Infrared Spatial Interferometer (Mount Wilson Obs., California).
- NPOI - Navy Prototype Optical Interferometer (Lowell Obs., Arizona). [Photos](#).
- PTI - Palomar Testbed Interferometer (Mount Palomar, California).
- SUSI - Sydney University Stellar Interferometer (Narrabri, Australia).

The following interferometers have ceased operations - the indicated dates are approximately the dates that the interferometers were operational: 20ft (1920-1931), 50ft (1931-1938), Intensity Interferometer (1964-1976), I2T (1974-1987), Mark I (1979), Mark II (1982-1984), 11.4m prototype (1985-1988), SOIR DETE (1979-1993), IRMA (1990-1992), Mark III (1986-1993), I2T/CHARON (1993-1996), and MIRA-I (1998-1999).

A [Timeline of Stellar Interferometry](#) from 1955 to the present shows the development of these interferometers.
